

## Build

Build is one of the basic life risk characteristics and one of the oldest. There is increased mortality at both extremes of weight as the graph below shows. The Center for Disease Control (CDC) reports that in 1999-2000 15% of American children and adolescents (ages 6-19) are overweight. For American adults, 64% are overweight or obese. Overweight conditions, or obesity, are often precursors to hyperlipidemia, diabetes, cardiovascular disease, or cancer. While an underweight condition may be normal, it may also be an indicator of an eating disorder or an underlying acute or chronic illness.

Those whose excess weight is muscle and bone, with little fat, and whose weight distribution is good are better risks than the obese. Body mass index (BMI) is a commonly used measurement of adiposity (fat as opposed to muscle) per height. The build table takes this into consideration by giving a weight range classified by height and BMI. Significantly overweight patients have an increased risk for coronary heart disease, diabetes, hypertension, and hyperlipidemia.

See page 2 which shows our build tables for adult's ages 18-64 and page 3 for ages 65 and over.
